Comp311 Assignment 8

Symbolic Evaluation of Boolean Expressions in Java

Due: 11:59pm Monday, Nov 15, 2021

200 points

Overview

Write a Java program that reduces boolean expressions (represented in the input and output streams in Racket-like notation) to simplified form. For the purposes of this assignment, boolean expressions are Racket expressions constructed from:

- the symbols T and F denoting the boolean values true and false;
- boolean variables (represented by symbols other than T, F, !, &, |, >, and ?) that can be bound to either true or false.
- the unary function! meaning not.
- the binary functions &, |, and > denoting and, or, and implies, respectively), and
- the ternary function? meaning if.

Note that the concrete (surface) syntax for boolean expressions differs from Assignment 5 in Racket because we are using the shorter names T, F, !, &, |, >, and ? are used instead of true, false, not, and, or, implies, and if for notational brevity, which matters in very large inputs. You can write your Java code to perform boolean simplification using either the interpreter pattern of the visitor pattern. The latter is perhaps slightly harder since there is more notational overhead, but it is valuable practice if you anticipate writing significant Java applications involving immutable inductively defined data

The course staff is providing

- the Java "stub" files in VisitorStub (**BoolSimp.java**, ...) provide a starting point for writing your solution using the visitor pattern, and
- the Java "stub" files in InterpreterStub (InterpBoolSimp.java, ...) provide a similar starting point for writing your solution using the interpreter pattern.

These stub files also include:

• a Java library file Parser.java (or InterpParser.java) containing a class Parser with

- a read() method that reads a boolean expression represented in concrete syntax ("Racket form"_ and returns the corresponding Java Form abstract syntax tree; and
- a reduce() method that composes the visitors (or "interpreter pattern" methods) you must write in BoolSimp.java (or InterpBoolSimp.java) to reduce whatever formula the Parser instance contains to simplified form.
- a conventional Java "stub" test file BoolSimpTest.java (or InterpboolSimpTest.java) that includes some rudimentary tests of the code in the BoolSimp.java (or InterBoolSimp.java) stub file. The visitor and interpreter versions of the stub files have different APIs so the two test files are not identical.
- a special Java "stub" test file BoolSimpFileTest.java (or interpBoolSimpFileTest.java) that test the solution code using external files (because the inputs are so I large) stored in a sibling directory called Data that is also included in the initial Assignment 8 repository.
- the file **boolsimp.rkt**, a complete solution to the programming problem (modulo minor differences in parsing and no external file support) written in Racket to serve as a basis for creating your Java solution.

You do not need to create any new files or directories. To support the proper file path names for our grading software, do not change any file or directory (folder) names.

The stub file <code>BoolSimp.java</code> (or <code>InterpBoolSimp.java</code>) includes comments showing you exactly what code you have to write to complete writing your simplifier. Of course, you also need to write corresponding tests and add them to the file <code>BoolSimpTest.java</code>. (or <code>InterpBoolSimpTest.java</code>). The contents of the provided test files are merely a starting point for your testing. You need to add comprehensive tests for each of the main operations in the simplifier

The file Parser.java (or InterpParser.java) is provided primarily to enable you to test your solution on large inputs stored in files. Parser.java includes two Parser constructors Parser(File file) and Parser(String form) for building parsers to parse the boolean expression (in concrete syntax form) in the specified File or String, respectively. Since the Java library class File is defined in the package java.io, which is not imported by default (unlike java.lang), you need to insert either

```
import java.io.*;
or more specifically
import java.io.File;
at the head of a test file that uses the Parser class on the contents of a file.
To construct a Parser for the formula in a file <fileName> you can invoke
new Parser(new File("<fileName>"));
```

If you omit the new File(...) wrapper around the String name of the file and simply use "<fileName>" instead, you will create a Parser for the String "<fileName>", which is then interpreted as a simple boolean variable. The File input medium is important because it

enables us to conveniently apply your simplifier to formulas that are thousands of symbols long. As a result, for this assignment you only have to translate the Racket code in boolsimp.rkt into corresponding cleanly-written OO Java code by filling in the gaps in our Java stub file boolSimp.java (or interpBoolSimp.java). You are expected to appropriately use the composite, interpreter, singleton, and visitor patterns in the code that you write. Since the only stub files that you have to modify are boolSimp.java (or interpBoolSimp.java) and boolSimpTest.java, simply create working versions of these files in the remote GitHub repository (github.com) for this assignment to "turn in" your assignment. Warning: we will run your program on large inputs to determine if you wrote the code correctly. Try using the large test files provided in the Data folder in your assignment repository.

All of the support files for this assignment are written in "Full" Java rather than functional Java because the functional Java translator embedded in DrJava was not designed to support non-trivial programs like this one. In principle, a very nice solution to this problem can be written in functional Java. If I happen to create a more robust implementation of the Functional Java translator next summer, future editions of this assignment may be conducted entirely in Functional Java. We expect you to write functional code (**no** mutation of data structures or the cells holding the bindings of variables). If you use DrJava as your IDE, make sure that the language is set to "Full Java".

The Racket file **boolSimp.rkt** includes Racket functions **parse** and **unparse** to translate Racket lists into abstract syntax trees and vice-versa. Racket provides a simple external syntax for lists (in homage to its LISP heritage) but Java does not. Hence the Java **Parser** class works on Java strings instead of lists. The Java visitor class **Print** in the **BoolSimp.java** file performs unparsing of the abstract syntax types **Form** and **IfForm** to type **String**.

As in Homework 5, the Racket parsing functions in **boolSimp.rkt** rely on the following Racket data definitions.

Given

```
(define-struct Not (arg))
(define-struct And (left right))
(define-struct Or (left right))
(define-struct Implies (left right))
(define-struct If (test conseq alt))
```

a **boolExp** is either:

- a boolean constant true and false;
- a symbol **S** representing a boolean variable;
- (make-Not X) where X is a boolExp;
- (make-And X Y) where X and Y are boolExps;
- (make-Or X Y) where X and Y are boolExps;
- (make-Implies X Y) where X and Y are boolExps; or
- (make-If X Y Z) where X, Y, and Z are boolExps.

Notes:

- 1. The **or** operator is written as \ | in Racket instead of | because | is a metasymbol with a special meaning in Racket.
- 2. In essence, **boolSimp.rkt** is a solution to Homework 5. The Java code in the file **Parser.java** assumes the input in written in Racket notation, but with the following abbreviations to shorten the length of formulas:

Abbreviation	Original Symbol
T	true
F	false
!	Not
&	And
1	0r
>	Implies
?	If

The Java abstract syntax classes include a separate composite hierarchy (called ifExp in boolSimp.rkt). This representation includes only three concrete variant classes, making it much easier to write the visitors that perform normalization, evaluation, and convert-To-Bool.

Hints on Writing Your Java Code

The visitor pattern is a powerful but notationally cumbersome alternative to the interpreter pattern. You can mechanically translate interpreter pattern code to visitor pattern code. (Perhaps IDEs like Eclipse should support such transformations.) The interpreter solution to this assignment is a bit easier to write than the visitor solution. If you are still learning Java mechanics, you are encouraged to write an interpreter solution first and perhaps translate it later to visitor form. A perfect visitor solution will be given 10 extra points over a perfect interpreter solution. If you submit an interpreter solution, your program must conform to class signatures given in the interpreter pattern support code below (just as a visitor solution must conform to the class signatures given in the visitor pattern code below).

The interpreter version of the support code replaces the **ConvertToIf**, **Normalize**, **HeadNormalize**, **Evaluate**, and **Print** visitors by methods named **convertToIf**, **normalize**, **headNormalize**, **eval**, and **print**. The files **Parser.java** and **InterpParser.java** contain references to these visitor class names and method names, respectively

Both the interpreter and visitor version use generic types but since the data input to the simplifier does not involve an parametric types (in contrast to in Assignment 7)

Support Code

Here are the links for the files:

- boolSimp.rkt is the reference Racket program.
- o <u>BoolSimp.java</u> is a stub program for a visitor solution.
- BoolSimpTest.java\ is a stub test file for a visitor solution.
- BoolSimpFileTest.java is a special test file for a visitor solution.
- o Parser.java is a parser file for a visitor solution.
- o InterpBoolSimp.java is a stub program for an interpreter solution.
- o interpBoolSimpTest.java is a stub test file for an interpreter solution.
- InterpParser.java is a parser file for an interpreter solution.

InterpParser.java is distinct from Parser.java because the code for the reduce method embedded in the parser is different in the two versions. Fortunately, in the empty package, the file containing a non-public class can have a different name than the class.bbbb

Sample Input Files

The following files contain large formulas that can be reduced by your simplifier. Only the files named **bigDatax** require a larger thread stack size than the JVM default on most platforms. **NOTE:** to handle the **bigDatax** files, you must set JVM argument **-Xss64M** for the Interactions JVM using the DrJava Preferences command on the Edit menu. The JVM argument setting can be found on the last panel (called JVMs) in the Preferences categories tree.

```
littleData1 -> "T"
littleData2 -> "T"
littleData3 -> "(> h (> g (> f (> e (> d (> c (! b))))))"
littleData4 -> "(> h (> g (> f (> e (| d (| c (| b a))))))"
bigData0 -> "T"
bigData1 -> "(> j (> i (> h (> g (> f (> e (| d (| c (| b a)))))))"
```
